Side Preferences among University Students in Japan and Korea

Surender KUMAR, Yong Seob KIM, Kun Seok OH

Abstract

Japanese and Korean 2nd year and 3rd year university students were examined on handedness, footedness, eyedness, earedness responses for unilateral activities using a scale sampling procedure on one time. Side-bias questionnaire was utilized to choose the activities for side preferences. Students exhibited strong hand and foot preferences, but not to the same extent in eye and ear sidedness preferences. Cultural effect was not emerged.

Introduction

Social sanctions usually influences the side preferences in hand, and behavioral oriented activities as seen globally. Mostly hand preferences is seen a social stigma in Asian countries, while the leg, eye and ear preferences do not become such issues interestingly. Parents usually point out for hand side use from infant to elementary school age, and many times exhibit a strong pressure to make use of the right hand as found in many Asian countries. Though the side influence on foot is relatively less; and hardly observed to be pointed out in eye and ear side use (Kumar, Kim, Oh, 2017). The normal process of side bias involves asymmetrical use of paired organs (like hand, foot, eye, and ear) for most behavioral functions. By side bias we mean preferential use of one side of the body as a function of preference or performance (Bryden, 1982; Mandal, Bulman-Fleming, & Tiwari, 2000). Side bias is considered important for the purpose of resource allocation and effective motoric-coping with the environment. The asymmetrical use of paired organs is primarily controlled by the two sides of the human brain. Since the left hemisphere is dominant for most individuals (about 90%), the contralateral side of the body (the right hand, the right foot) is more preferred for motor functions. The right hemisphere controls the left side of the body, and the left hemisphere controls the right side. In most people, the left hemisphere regulates language and speech, and the right hemisphere controls nonverbal, spatial skills. If the right side of the brain is damaged, movement of the left arm and leg, vision on the left, and/or hearing in the left ear may be affected. Injury to the left side of the brain affects speech and movement on the right side of the body. Each half of the brain is divided into main functional sections, called lobes. There are four lobes in each half of the brain: the Frontal Lobe, Temporal Lobe, Parietal Lobe, and Occipital Lobe. Other important sections of the brain are
the Cerebellum and the Brain Stem. Although not usually divided into lobes, the cerebellum and brain stem both have different parts. Each of the brain hemispheres and lobes, cerebellum, and brain stem has specific functions, and they all work together: Frontal Lobe: most anterior, right under the forehead; the frontal lobe controls intellectual activities, such as the ability to organize, as well as personality, behavior, and emotional control. Parietal Lobe: near the back and top of the head above the ears; the parietal lobe controls the ability to read, write, and understand spatial relationships. Occipital Lobe: most posterior, at the back of the head; the occipital lobe controls sight. Temporal Lobe: side of head above ears situated immediately behind and below the frontal lobes; the temporal lobe controls memory, speech and comprehension. Brain Stem: lower part of brain, leads to spinal cord; the brain stem contains nerve fibers that carry signals to and from all parts of the body. The brain stem also regulates body functions such as consciousness, fatigue, heart rate, and blood pressure. Damage to the brain stem can cause loss of consciousness. Cerebellum: located at the base of the skull; it is a curved mass of nerve tissues that regulates balance and coordinates fine motor skills; it enables us to move quickly and smoothly. Grey and White Matter: The brain is made up of two types of tissue, grey matter and white matter. Grey matter is involved in analyzing information. White matter conducts information between grey matter areas. The ratio of grey to white matter changes over the lifespan (Northeastern.edu, 2010).

The landmark work by Geschwind – Behan – Galaburda (Geschwind & Behan, 1982; Geschwind & Galaburda, 1986), known as G-B-G model, implicated anomaly in hemispheric dominance associated with neurodevelopmental disorders including autism. Subsequently studies were conducted to examine the GBG model with all forms of developmental disorders too. The general findings suggested a left hemisphere dysfunction associated with the disorders while some researchers also suggested atypical dominance indicating lack of dominance in either hemisphere of the brain (see Bishop, 1990).

Keeping these issues in view, we examined hand, foot, eye, and ear preference of university students using a self-rated scale method and the cultural effect in Japanese and Koran situations. We decided to examine side bias through this method to ensure the consistency in performance of an activity. Footedness was included as a measure to examine side bias in long limbs, in general. Foot behavior, unlike handedness, is not subjected to social sanctions, less likely the eye, and least likely the ear subjected to the social sanctions, therefore are found to be a reliable indicator of side bias. It would be interesting to examine the cultural effect on side preference. Therefore, this study included the Japanese and Korean sample. We predicted anomalous side bias for disorders and in generals, based on the proposition of GBG model (Geschwind & Behan, 1982; Geschwind & Galaburda, 1986).
Method

Sample

University second year and third year students in Japan and Korea were considered for the study. The students did not have any apparent motor difficulty that may hinder their daily functioning or any kind of disability or disease in hand, foot, eye, and ear. A brief introduction of the study was given to the students and informed consents were taken prior to administer the study questionnaire. They were asked to rate the items as per their own recognitions and feelings as they use in their day to day life to avoid any initial pressure of changing their hand, foot, eye, ear preferences.

The Japanese participants were female students (2nd year, N=227, Mean age 19.3 yr., SD=.51; 3rd year, N=77, Mean age 20.4 yr., SD=.48). The Korean participants were male and female students (2nd year, N=26, Mean age 22 yr., SD=1.63; 3rd year, N=34, Mean age 24 yr., SD=1.11). Both the country students also did not have any other kind of motor problem or mental health problem as none of them reported.

Tools & Procedure

Japanese and Korean version of the Questionnaire for Hand-Foot-Eye-Ear Preferences (QHFEEP) were administered among the students. There were total 26 items in the scale. 10 items on handedness, 6 items on footedness, 5 items on eyedness and 5 items on earedness. They were asked to rate each item information as they use their right side (R) or left side (L) in day to day life. Laterality quotient was not studied.

The questions Included in the hand preference activities were (a) using a chopstick, (b) combing hair, (c) picking up a book from a rack, (d) picking up a suitcase, (e) brushing teeth, (f) throwing a ball to hit target, (g) unscrewing a jar lid, (h) using an eraser on paper, (i) hammering a nail, and (j) writing on paper. The foot behavior was also rated. Included in these activities were (a) kicking a ball, (b) picking up a pebble with toes, (c) stumping on an insect, (d) stepping up on a chair, (e) first foot use when climbing stairs, and (f) foot use when start riding a cycle. The eyedness included as (a) seeing in a telescope, (b) seeing in a pipe, (c) seeing into a bottle, (d) seeing into a narrow slit, and (e) seeing through the door peephole. The earedness included as (a) listen to a phone call, (b) listening to a small unclear voice, (c) listening to a voice coming from your back side, (d) putting an earphone, and (e) listening to a small voice coming from a closed room. The items were newly framed and some were part of a Side Bias Questionnaire which was earlier validated in other countries including Japan (Ida et al., 2001; Mandal et al., 1992; Mandal et al., 2001). Questionnaire items were self-rated by the participants and third person observers were not included.
Results & Discussion

The mixed data on right and left hand preference response rating for each subject was averaged across items for handedness, footedness, eyedness, and earedness separately, and in total. These scores were then loaded for percentage calculations for each subject. The mean scores were not calculated as the items were marked on, right side as labelled 1, and left side as labelled 2. Table 1 suggests the handedness, footedness, eyedness, and earedness pattern of each subject. Side preferences of Japanese students were found to be in total of hand, foot, eye, and ear was 80.49% the right side preference; and 19.51% the left side preference. The total preference was similar to that of any Asian country.

On handedness, 3rd year students exhibited slightly more use (16.62%) than 2nd year students (15.22%) in left side. On right side, 2nd year students showed more use (86.78%) than 3rd year students (83.34%). In total, left side was 14.08%, and right side was 85.92%. The finding is a sharp departure of what we observe in any population. About 90% of the human population is said to be right handed. The incidence of left-handedness has been found to be as low as four to six percent in traditional societies like Asia and Africa (for example, India 6.8%; Mandal, Pandey, Singh, & Asthana, 1992; Japan 4.7%; Ida, Dutta, & Mandal, 2001), while in modern societies like the United States, Canada, and England it averages at 15-20% (Perelle & Ehrman, 1994; Suar, Misra, Mandal, & Suman, 2008). The study hand preferences were close to the European or American preferences.

On footedness, 3rd year students did not differ (13.42%) than 2nd year students (12.63%) in left side use. On right side also, 3rd year students did not differ (86.58%) than 2nd year students (87.37%). In total, left side was 12.83%, and right side was 87.17%. Again the footedness results were close to the handedness. Foot preferences were more reliable without much influence of social behaviour restrictions or sanctions.

On eyedness, 3rd year students did differ at large extent (24.68%) than 2nd year students (28.55%) in left side use. On right side also, 3rd year students differed (75.32%) than 2nd year students (71.45%). In total, left side was 27.57%, and right side was 72.43%. Eyedness results also did not altered by social behaviour constraints. Eyedness results showed that side use is not so much related to the handedness or footedness. Use of eye though was preferred as per the side but strongly rated greater than on hand or foot use.

On earedness, 3rd year students did differ remarkably (34.03%) than 2nd year students (29.07%) in left side use. On right side also, 3rd year students differed (65.97%) than 2nd year students (70.93%). In total, left side was 30.33%, and right side was 69.67%. Ear sidedness results also did not altered much by social behaviour constraints or sanctions and a frequent use of ear was shown without considering the side bias, though right hand preference students rated more the right ear use. Earedness results showed that side use is not so much related to the handedness or footedness or

eyedness. Use of ear was also preferred as per the side but remarkably rated greater than on hand or foot use.

Japanese context study findings exhibited the trend that there are more chance that handedness was strongly influenced on side-bias, footedness relatively less influenced by side-bias, eyedness very less influenced by side-bias, and earedness was least influenced by the side-bias. The side preferences were greater than the Asian countries and slightly less than the European countries.
Side preferences of Korean students were found to be in total of hand, foot, eye, and ear was 78.65% 
the right side preference and 21.35% the left side preference. The total preference was similar to 
that of any Asian country. The Korean students’ mean age was found higher than the Japanese 
students. It is because of the compulsory military service of 25 months and that was the main 
reason for the mean age difference.

On handedness, 2nd year students exhibited high use (25.38%) than 2nd year students (14.41%) in left 
side. On right side, 3rd year students showed more use (85.59%) than 2nd year students (74.62%). In 
total, left side was 19.17%, and right side was 80.83%. The finding is again a sharp departure of what 
we observe in any population. About 90% of the human population is said to be right handed. The 
incidence of left-handedness has been found to be as low as four to six percent in traditional societies 
like Asia and Africa (for example, India 6.8%: Mandal, Pandey, Singh, & Asthana, 1992; Japan 4.7%: 
Ida, Dutta, & Mandal, 2001), while in modern societies like the United States, Canada, and England it 
averages at 15-20% (Perelle & Ehrman, 1994; Suar, Misra, Mandal, & Suman, 2008). The study hand 
preferences were close to the European or American preferences.

On footedness, 2nd year students also differed (26.28%) than 3rd year students (14.71%) in left side 
use. On right side also, 3rd year students differed (85.29%) than 2nd year students (73.72%). In total, 
left side was 19.72%, and right side was 80.28%. Again the footedness results were close to the 
handedness. Foot preferences were more reliable without much influence of social behaviour 
restrictions or sanctions.

On eyedness, 3rd year students did differ at large extent (11.76%) than 2nd year students (32.31%) in 
left side use. On right side also, 3rd year students differed (88.23%) than 2nd year students (67.69%). 
In total, left side was 20.67%, and right side was 79.33%. Eyedness results also differed in greater 
extent. Eyedness references showed that side use is not so much related to the handedness or 
footedness. In this study the eye use though was preferred as per the side but strongly rated 
greater than on hand or foot use. Other way, the eye side use ratings were not altered by social 
sanctions.

On earedness, 3rd year students did differ (23.53%) than 2nd year students (34.62%) in left side use. 
On right side also, 3rd year students differed (65.38%) than 2nd year students (76.47%). In total, left 
side was 28.33%, and right side was 71.67%. Ear sidedness results also did not altered much by social 
behaviour constraints or sanctions and a frequent use of ear was shown without considering the 
side bias, though right hand preference students rated more the right ear use. Earedness results 
showed that side use is not so much related to the handedness or footedness or eyedness. Use of ear 
was also preferred as per the side but remarkably rated greater than on hand or foot use.

Korean context study findings exhibited the trend that there are more chance that handedness 
was strongly influenced on side-bias in 3rd year students only, footedness relatively less influenced by 
side-bias, eyedness very less influenced by side-bias, and earedness was least influenced by the side-
bias. The side preferences were close to the European countries.

The cultural difference was not reflected among both the countries as similar pattern of observed in both the data. These findings reflects that people feel strong social constraints or social sanctions on handedness, and noticeably less influence on footedness as a social constraints or sanctions factor though the better rated on right footedness may be influenced by the habitual or biological factors rather than the social behavioral pressures. The eyedness and earedness were also least affected by social behavior pressures and one can feels that side use of eye and ear is hardly pointed out or exert a pressure to be noted by the parents or by the surrounding people. Eyedness and earedness were better rated on right that may also be considered to be a habitual or biological factor and least likely to be altered by social sanctions.

The Japanese and Korean findings thus support the original conjecture of GBG Model (Geschwind & Behan, 1982; Geschwind & Galaburda, 1986) which indicated anomalous dominance or side bias. The GBG Model proposed that high intrauterine hormonal exposure, especially testosterone, alters natural cerebral dominance pattern to individuals resulting in anomalous side dominance. The hormonal exposure also alters the brain structures like thymus which, in turn, cause damage to immune system. Large data findings in Korean context is a left task for further study. There are other certain factors to be taken account as by whom the hand side preference was recommended, side preferences at five anchor rating, medical causes, side preferences in right and left handers separately, etc. to be investigate in further study.

Anomalous dominance pattern has been observed in other studies as well with a somewhat different notion. For example, in deaf children, anomalous hand dominance has been reported (Mandal et al., 1999). Language deficit is also found to be associated with atypical handedness in mental retardation (Lucas et al., 1989). These studies link atypical or anomalous handedness with reduced activation in the dominant hemisphere or some form of pathology in the brain including early cerebral insult. The use of side preferences was found different in the children with developmental disorders (Kumar et. al, 2010). Though some social prepositions are there to points out to the phenomenon which seems to be invariant to cultural predisposition. To avoid cultural predisposition, footedness was included as a measure of side bias. In a recent study it has been found that there is a clear interrelatedness between the long limbs (hand, foot) with the cerebral lateralization pattern (Kumar et al., 2012), pointing out to a common biological mechanism for side bias including eyedness and earedness.
